## 2 Phase Buck Controller with Integrated Gate Drivers and AVP

The NCP5383 is a two phase buck controller used in low voltage, high current power supplies. Dual-edge pulse-width modulation (PWM) combined with inductor current sensing and adaptive voltage positioning (AVP) reduces system cost by providing the fastest initial response to transient loads thereby requiring less bulk and ceramic output capacitors to satisfy transient load-line requirements.

A high performance operational error amplifier is provided, which allows for easy compensation of the system. Protection features include overcurrent protection, undervoltage lockout (UVLO), thermal shutdown and power good monitor.

### Features

- Dual-edge PWM for Fastest Initial Response to Transient Loading
- High Performance Operational Error Amplifier
- 1% Internal Reference Voltage Accuracy
- Phase-to-Phase Current Balancing
- “Lossless” Differential Inductor Current Sensing
- Differential Current Sense Amplifiers for Each Phase
- Adaptive Voltage Positioning (AVP)
- Frequency Range: 100 kHz – 400 kHz Set by the Resistor
- Power Good Output with Internal Delays
- Programmable Soft Start Time
- Integrated Gate Drivers
- This is a Pb-Free Device

### Applications

- Pentium IV Processors
- Graphics Cards
- Low Voltage, High Current Power Supplies

## PIN DESCRIPTIONS

Pin No.	Symbol	Description
1	R <sub>OSC</sub>	A resistance from this pin to ground programs the oscillator frequency according to $f_{sw} = 1 / (R_{OSC} \cdot 100 \text{ pF})$ . Also, this pin supplies a trimmed output voltage of 2.00 V so it may be used to form a voltage divider at the I <sub>LIM</sub> pin to set the over current shutdown threshold as shown in the Applications Schematics.
2	I <sub>LIM</sub>	Over current shutdown threshold. To program the shutdown threshold, connect this pin to the R <sub>OSC</sub> pin via a resistor divider as shown in the Applications Schematics. To disable the over current feature connect this pin directly to the R <sub>OSC</sub> pin. To guarantee correct operation, this pin should only be connected to the voltage generated by the R <sub>OSC</sub> pin – do not connect this pin to any externally generated voltages.
3	V <sub>CC</sub>	Power for the internal control circuits.
4	AGND	Power supply return for the analog circuits that control output voltage.
5	SS	A capacitor from this pin to ground programs the soft-start time.
6	COMP	Output of the error amplifier and input to the inverting pin of the PWM comparators.
7	V <sub>FB</sub>	Voltage feedback pin and error amplifier inverting input. Connect a resistor from this pin to V <sub>CORE</sub> . The value of this resistor and the amount of current from the droop resistor (R <sub>DRP</sub> ) will set the amount of output voltage droop (AVP) during load.
8	V <sub>DRP</sub>	Current signal output for Adaptive Voltage Positioning (AVP). The offset of this pin above the no-load set-point is proportional to the output current. Connect a resistor from this pin to V <sub>FB</sub> to set the amount of AVP current into the feedback resistor (R <sub>FB</sub> ) that will result in output voltage droop. Leave this pin open for no AVP.
9	CS <sub>x</sub>	Non-inverting input to current sense amplifier #x, x = 1, 2
10	CS <sub>xN</sub>	Inverting input to current sense amplifier #x, x = 1 (Tie to V <sub>CORE</sub> )
12	EN	When this pin is pulled High the controller is enabled. When it is pulled Low the controller will be disabled. Either an open-collector output (with a pull-up resistor) or a logic gate (CMOS or totem-pole output) may be used to drive this pin. A Low to High transition on this pin will induce soft start. If the Enable function is not required, this pin should be tied directly to V <sub>CCP</sub> .
18	V <sub>CCP</sub>	Power for the gate drivers
19, 17	BG	Bottom gate MOSFET driver pin. Connect this pin to the gate of the bottom N-channel MOSFET.: Phase #x, x = 1, 2
20, 16	PGND	Ground reference for the bottom gate drivers
21, 15	SWN	Switch node pin. This is the reference for the floating top gate driver. Connect this pin to the source of the top MOSFET. : Phase #x, x = 1, 2
22, 14	TG	Top gate MOSFET driver pin. Connect this pin to the gate of the top N-channel MOSFET. : : Phase #x, x = 1,2
23, 13	BST	Supply rail for the floating top gate driver. To form a boost circuit, use an external diode to bring the desired input voltage to this pin (cathode connected to BST pin). Connect a capacitor (CBST) between this pin and the PHASE pin. Typical values for CBST range from 0.1 μF to 1 μF. Ensure that CBST is placed near the IC.: Phase #x, x = 1, 2.
24	PG	PowerGood output. Open drain type output with internal delays. The output is latched low if V <sub>fb</sub> is 125% of V <sub>FB</sub> or 75% of V <sub>FB</sub> .

## ABSOLUTE MAXIMUM RATINGS

Rating	Value	Unit
Operating Ambient Temperature Range	0 to 70	°C
Operating Junction Temperature Range	0 to 125	°C
Storage Temperature Range	-55 to 150	°C
Lead Temperature Soldering, Reflow (60 second maximum above 183°C):	230	°C
Thermal Resistance, Junction-to-Ambient ( $R_{\theta JA}$ ) on a thermally conductive PCB in free air	56	°C/W
ESD Susceptibility (Human Body Model)	2.0	kV
JEDEC Moisture Sensitivity Level	1	MSL
Maximum Voltage $V_{CC}$ with respect to AGND	13.2	V
Maximum Voltage $V_{CCP}$ and all other pins with respect to ground	5.5	V
Maximum Voltage $V_{BST}$ and all other pins with respect to ground	18.7	V
Maximum Voltage $V_{BST}$ and all other pins with respect to SWN	5.5	V
Maximum Voltage SWN and all other pins with respect to ground	3.0	V
Minimum Voltage SWN and all other pins with respect to ground	-2.0	V
Minimum Voltage all pins with respect to ground	-0.3	V
Maximum Current into pins: COMP, $V_{DRP}$	3.0	mA
Maximum Current out of pins: COMP, $V_{DRP}$ , $R_{OSC}$ , SS	3.0	mA

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

## APPLICATIONS INFORMATION

### General

The NCP5383 dual edge modulated multiphase PWM controller is specifically designed with the necessary features for a high current power system. The IC consists of the following blocks: High Performance Voltage Error Amplifier, Precision Oscillator and Triangle Wave Generators, and PWM Comparators. Protection features include Undervoltage Lockout, Soft-Start, Overcurrent Protection, Thermal Shutdown and Power Good Monitor.

### High Performance Voltage Error Amplifier

The error amplifier is designed to provide high slew rate and bandwidth. A capacitor from COMP to  $V_{FB}$  is required for stable unity gain test configurations.

### Oscillator and Triangle Wave Generator

A programmable precision oscillator is provided. The oscillator's frequency is programmed by the resistance connected from the  $R_{OSC}$  pin to ground. The user will usually form this resistance from two resistors in order to create a voltage divider that uses the  $R_{OSC}$  output voltage as the reference for creating the current limit setpoint voltage. The oscillator frequency range is 100 kHz/phase to 400 kHz/phase. The oscillator generates 2 triangle waveforms (symmetrical rising and falling slopes) between 1.3 V and 2.3 V. The triangle waves have a phase delay between them such that for 2 phase operation the PWM outputs are separated by 180 degrees.

### PWM Comparators with Hysteresis

Two PWM comparators receive the error amplifier output signal at their non inverting input. Each comparator receives one of the triangle waves offset by 1.3 V at its inverting input. During steady state operation, the duty cycle will center on the valley of the triangle waveform, with steady state duty cycle calculated by  $V_{out}/V_{in}$ . During a transient event, both high and low comparator output transitions shift phase to the points where the error amplifier output intersects the down and up ramp of the triangle wave.

## PROTECTION FEATURES

### Undervoltage Lockout

An undervoltage lockout (UVLO) senses the  $V_{CC}$  input. During powerup, the input voltage to the controller is monitored, and the PWM outputs and the soft-start circuit are disabled until the input voltage exceeds the threshold voltage of the UVLO comparator. The UVLO comparator incorporates hysteresis to avoid chattering, since  $V_{CC}$  is likely to decrease as soon as the converter initiates soft-start. There is a separate undervoltage lockout (UVLO) for the drivers that sense the  $V_{CCP}$  inputs.

### Overcurrent Shutdown

A programmable overcurrent function is incorporated within the IC. A comparator and latch makeup this function. The inverting input of the comparator is connected to the ILIM pin. The voltage at this pin sets the maximum output current the converter can produce. The ROSC pin provides a convenient and accurate reference voltage from which a resistor divider can create the overcurrent setpoint voltage. Although not actually disabled, tying the ILIM pin directly to the ROSC pin sets the limit above useful levels – effectively disabling overcurrent shutdown. The comparator non inverting input is the summed current information from the current sense amplifiers. The overcurrent latch is set when the current information exceeds the voltage at the ILIM pin. The outputs are immediately, and the soft-start is pulled low. The outputs will remain disabled until the  $V_{CC}$  voltage is removed and re-applied, or the ENABLE input is brought low and then high.

### Power Good Monitor

NCP5383 has a power good monitor set at 125% of  $V_{fb}$  or 75% of  $V_{fb}$  for upper and lower thresholds respectively. It is an open drain type output.

### Soft-Start

The NCP5383 incorporates an externally programmable soft-start. The soft-start circuit works by controlling the ramp-up of the  $V_{ref}$  voltage during powerup. The initial soft-start pin voltage is 0 V. The soft-start sequence ends when  $V_{SS} = 0.8$  V. The soft-start pin is pulled to 0 V if there is an overcurrent shutdown, if  $V_{CC}$  is below the UVLO threshold, or if  $V_{CCP}$  is below the UVLO threshold.

### Programming the Current Limit and Oscillator Frequency

The OSC pin provides a 2.0 V reference voltage which is divided down with a resistor divider and fed into the current limit pin ILIM. Calculate the total series resistance to set the frequency and then calculate the individual values for current limit divider. The series resistors RLIM1 and RLIM2 sink current to ground. This current is internally mirrored into a capacitor to create an oscillator. The period is proportional to the resistance and frequency is inversely proportional to the resistance.

Figure 18. ROSC vs. Phase Frequency

$$V_{LIMIT} \cong 5.94 \cdot \left( I_{MIN\_OCP} \cdot DCRT_{max} + \frac{DCR_{50C} \cdot V_{out}}{2 \cdot V_{in} \cdot F_s} \cdot \left( \frac{V_{in}-V_{out}}{L} - (N-1) \cdot \frac{V_{out}}{L} \right) \right) - 0.02 \quad (eq. 2)$$

Solve for the individual resistors:

$$RLIM2 = \frac{V_{LIMIT} \cdot ROSC}{2 \cdot V}$$

$$RLIM1 = ROSC - RLIM2 \quad (eq. 3)$$

**Final Equation for the Current Limit Threshold**

$$I_{LIMIT}(T_{inductor}) \cong \frac{\left( \frac{2 \cdot V \cdot RLIM2}{RLIM1 + RLIM2} \right) + 0.02}{5.94 \cdot (DCR_{25C} \cdot (1 + 0.00393 \cdot C^{-1}(T_{Inductor}-25 \cdot C)))} - \frac{V_{out}}{2 \cdot V_{in} \cdot F_s} \cdot \left( \frac{V_{in}-V_{out}}{L} - 1 \cdot \frac{V_{out}}{L} \right) \quad (eq. 4)$$

Selecting the closest available values of 16.9 KΩ for RLIM1 and 15.8 KΩ yield a nominal operating frequency of 305 KHz and an approximate current limit of 180 A at 100C. The total sensed current can be observed at the VDRP pin added to a positive, no-load offset of approximately 0.8 V.

**Inductor Selection:**

When using the inductor current sensing it is recommended that the inductor does not saturate by more than 10% at the maximum load. The inductor also must not go into hard saturation before current limit trips. Small DCR values can be used, however current sharing accuracy and droop accuracy decrease as DCR decreases.

**Inductor Current Sense Compensation**

The NCP5383 uses the inductor current sensing method. This method uses an RC filter to cancel out the inductance of the inductor and recover the voltage that is the result of the current flowing through the inductor’s DCR. This is done by matching the RC time constant of the current sense filter to the L/DCR time constant. The first cut approach is to use a 0.47 μF capacitor for C and then solve for R.

$$R_{sense}(T) = \frac{L}{0.47 \cdot \mu F \cdot DCR_{25C} \cdot (1 + 0.00393 \cdot C^{-1} \cdot (T-25 \cdot C))} \quad (eq. 5)$$

Calculate the current limit voltage:

The current limit function is based on the total sensed current of two phases multiplied by a gain of 5.94. DCR sensed inductor current is function of the winding temperature. The best approach is to set the maximum current limit based on the expected average maximum temperature of the inductor windings.

$$DCRT_{max} = DCR_{25C} \cdot (1 + 0.00393 \cdot C^{-1}(T_{Tmax}-25 \cdot C)) \quad (eq. 1)$$

Figure 19.

The demoboard inductor measured 950 nH and 0.75 mΩ at room temp. The actual value used for Rsense matches the equation for Rsense at approximately 50C. Because the inductor value is a function of load and inductor temperature final selection of R is best done experimentally on the bench by monitoring the Vdroop pin and performing a step load test on the actual solution.

It is desirable to keep the Rsense resistor value below 1.0 k whenever possible by increasing the capacitor values in the inductor compensation network. The bias current flowing out of the current sense pins is approximately 100 nA. This current flows through the current sense resistor and creates an offset at the capacitor which will appear as a load current at the Vdroop pin. A 1.0 k resistor will keep this offset at the droop pin below 2.5 mV.

**Simple Average PSPICE Model**

A simple state average model shown in Figure 20 can be used to determine a stable solution and provide insight into the control system.

Figure 20.

**Droop Injection**

The VDRP signal is generated by summing the sensed output currents for each phase and applying a gain of approximately six. VDRP is externally summed into the feedback network by the resistor RDRP. This induces an offset which is proportional to the output current thereby forcing the controlled resistive output impedance.

RRDP determines the target output impedance by the basic equation:

$$\frac{V_{out}}{I_{out}} = Z_{out} = \frac{R_{FB} \cdot DCR \cdot 5.94}{RDRP} \quad (\text{eq. 6})$$

$$RDRP = \frac{R_{FB} \cdot DCR \cdot 5.94}{Z_{out}}$$

**Thermal Shutdown**

The NCP5383 also provides Thermal Shutdown (TSD) for added protection. The TSD circuit monitors the die temperature and turns off the top and bottom gate drivers if an over temperature condition is detected. The internal soft-start capacitor is also discharged. This is a latched state and requires a power cycle to reset.
